fullText:

PMs are least threatened by AI; it's a tool to speed research, draft PRDs, and assist, while strategic/creative skills, stakeholder alignment, and team dispute resolution remain human-led. Author describes leading a SaaS marketplace from zero to V1 and pivoting strategy; AI assisted but did not drive strategy, UI vision, GTM, branding, investor outreach, or people issues. Notes that in big orgs with limited strategic ownership, more execution-heavy PM roles could feel threatened by AI.

contentSnippet:

PMs are least threatened by AI; it's a tool to speed research, draft PRDs, and assist, while strategic/creative skills and cross-functional alignment remain human-led. AI helped but did not drive strategy or GTM; execution-heavy PM roles may be at higher risk.

fullText:

Evals are critical. Built a simple support bot with proper evaluations. Findings: Vendors warn you not to trust LLMs without evals (hallucinations risk). Most work was manual labeling in Sheets. LLM failed basic logic (45<60) only caught via human review. Automated LLM judge initially useless (overrated everything); 20% tone match to humans until tuned. Negative user feedback can reflect policy, not model failure. Reality of evals: constant iteration; define what “good” looks like and measure continuously.

contentSnippet:

Evals are critical to mitigate hallucinations and logic errors. Manual labeling matters; automated LLM judges misalign with humans; metrics can mislead.

<https://www.linkedin.com/posts/shalini-priyadarshini-llms-hallucinate-voicebots-activity-7372>

fullText:

Why do LLMs still hallucinate? In voicebots, clients ask if they can trust it won't make things up. Benchmarks reward guessing over honesty; models learn to bluff. Accuracy isn't reliability. Errors should be treated differently than abstentions — "I don't know" should be a feature. Fix incentives and evals to reduce hallucinations; wrong refund amounts in voicebots can be disastrous.

contentSnippet:

Hallucinations persist due to eval/training incentives; PMs need abstention strategies and better eval design for reliability-critical use cases like voicebots.

fullText:

One of the first things I learned in product management back in 2016/17 was the ABCs. Over the years, after delivering dozens of different products, I discovered that these ABCs - Alignment, Balance, and Communication were the true differentiators between a good product manager/leader and a great one. But I think the Old ABCs of Product Management Aren't Enough in 2025. Alignment meant ensuring my team, stakeholders, and customers were all rowing in the same direction. Every feature, sprint, or roadmap decision had to tie back to the bigger picture: business strategy and real user needs. Without alignment, even the best ideas lost momentum. Balance meant managing trade-offs — speed vs. quality, short-term wins vs. long-term vision, business goals vs. user value. Getting it right meant delivering sustainable impact, not just outputs. Communication meant turning complexity into clarity. As product managers and leaders, we became the bridge between data, engineering, design, leadership, and customers. Strong communication held alignment together and made balance possible. These ABCs built the foundation of my career. But here's what I've come to realise: Every product manager and product leader knows the ABCs. But in 2025, at the peak of the AI era, relying only on the old ABCs feels like bringing a knife to a gunfight. The New ABCs for the AI-First Product Manager and Leader. Back in 2017, Alignment was about people moving in sync. In 2025, it's about AI-Native Adaptability. Today, we must think in AI: translate product goals into model capabilities, understand risks like bias or hallucination, and use GenAI to accelerate research and prototyping. The PM who once aligned humans must now align humans and machines. Balance, once about trade-offs, has evolved into Beyond the Build. In AI-first products, shipping features isn't enough, what matters is impact. Are they improving retention, NPS, revenue, or trust? In 2023, 80% of AI features shipped were underused or misunderstood. That taught me a simple truth: one correct Outcome outweighs dozens of wrong Outputs. And Communication has transformed into Collaborative Co-Creation. It's no longer just about simplifying ideas for teams. Today, we co-create with users through feedback loops, with teams across functions, and even with AI itself — ChatGPT, Figma AI, Notion AI. The modern product toolkit now includes skills I never imagined when I started: prompt engineering, model evaluation, and user trust design. Products now move from idea to prototype in days, not months. The old ABCs gave us the foundation. The new ABCs give us the future. Because in the AI era, the

difference between a good product manager/leader and a great one isn't what you know, it's how bravely you evolve.#ProductManagement #AI #Innovation #Leadership #FutureOfWork

fullText:

Product management thinking is what helped me overcome AI's biggest limitations this week. On Monday, I hit a wall. I've been working on some long-form writing with the help of ChatGPT and finally ran into the context window limit. I had already managed to stretch things pretty far with creative summarization prompts, but I realized I was spending more time managing summaries and curating what went into them than actually writing. I needed a better tool. On Tuesday, I started designing a long-form writing assistant built with persistent memory. By Thursday, I had a working prototype. It includes a text editor, structured document hierarchy, autosave, versioning, document status, and a backend built on Supabase. The DB supports chunked writing units, embedded metadata, and flexible scene organization. I am now moving into the next phase, building a memory system using vector search and RAG techniques so the AI can access relevant context across long documents. Then, I will start layering in AI-assisted writing tools designed to keep users focused on content instead of managing prompts and context windows. I went from idea to working prototype in just two days. But that speed doesn't mean complexity disappears. AI tools work well when the project is simple. As complexity grows, they begin to falter. Prompts become harder to maintain. Generated code gets inconsistent. Small changes introduce instability. That is when structure becomes critical. To manage this, I organized features into modular, self-contained groups, each one built around a clear goal, much like how I would plan a sprint. This helped isolate the complexity that AI had to deal with at any given time. I also mapped out the order of implementation carefully, based on dependencies. This kept the foundation clean and made sure later features did not require rework. These decisions were not about writing code. They were about managing complexity. And that is where product thinking is the magic bullet. Documentation, modular design, reusable prompt patterns, and sequencing based on dependencies are all standard product practices. In an AI-powered workflow these prevent chaos. The tools will generate code, but they're still very sloppy about creating the architecture. About planning for the future. That is still our job. The process felt familiar. Fast feedback, thoughtful planning, and strong boundaries around complexity. The tools were new, but the approach was not. What is changing is the distance between product and development. It is shrinking. With clear planning, a good understanding of systems, and the ability to communicate well with AI tools, it is now possible to go from concept to working app in days. I believe we are on the edge of a major shift in how PMs work. The tools are here. The real question is whether we are ready to use them well. I truly believe that in 1-2 years product and development are going to merge into a single role assisted by AI.

I built one! I approached AI the same way I approached the use of automation: use it where it delivers real, tangible value. And no we aren't doing a chatbot anytime soon lol We started by mapping all the core interactions across our product and simply asked, 'Would this benefit from AI?' That question sounds straightforward, but it opens a can of interesting deeper conversations about user intent, friction, latency, and even emotion. If you have a UX team they are incredible for these conversations. The answer a lot of times was 'maybe but first fix these core infrastructure issues so we make sure we have good data to use with ai' From there, we prioritized areas where AI could simplify complexity, speed up time to value, or make users feel more confident and in control. Surprise like most people, we don't actually have that much ai embedded yet but we have a good list of areas to improve and with those improvements can put ai to work for the people using our products Sam Altman in a recent interview with Theo Von said something about how if ai is running properly you shouldn't even know it is there. That really resonated with me
